Abstract

Introduction: Central Nervous Tumors constitute 3% of cancer cases worldwide. The incidence of CNS tumors in India ranges from 5-10 per 100,000 population, ranking 14th among all other tumors and accounting for 2% of malignancies. The five most frequent tumors were astrocytoma (47.3%), Medulloblastoma (11.4%), craniopharyngioma (9.7%), ependymal tumors (4.8%), and nerve sheath tumors (4.1%). The tumor spectrum varies among different ages and sexes.

Materials and Methods: All the patients of CNS tumours who attended the Department of Radiation Oncology, SAMC, and PGI from October 2010 to December 2019 are included in the study. The medical records of 238 patients were evaluated, out of which only 102 were fit for the study as per the inclusion and exclusion criteria.

Results: The 3-year median overall survival (OS) of 8 years and Progression Free Survival (PFS) of 7 years, while the 5-year median OS of 9 years and PFS of 7 years is recorded. Glioblastoma (GBM) is the most aggressive out of all histologies, with a 2-year survival of 31% and a median OS of 8 months, as per our study. We got some good results with brainstem glioma as well, with a 2-year survival of 40% and a median OS of 18 months.

Conclusion: The survival in CNS tumours has improved widely with adjuvant concurrent chemoradiation postoperatively, and the better the resection is done, the better the survival is seen.

INTRODUCTION

Central Nervous Tumors (CNS) constitute 3% of cancer cases worldwide. The incidence of CNS tumors in India ranges from 5-10 per 100,000 population, ranking 14th among all other tumors and accounting for 2% of malignancies.¹ According to Global Cancer Incidence, Mortality and Prevalence (GLOBOCAN) 2020, an incidence of 308102 new cases of CNS were reported, ranking 20th among all other tumors, causing 251329 deaths

and 5-year survival of 837152.² The types of Primary Brain Tumors are Gliomas and Non-Gliomas. The Gliomas include Astrocytoma, Oligodendrogliomas, Ependymoma, and Brain Stem Glioma. The Non-Gliomas include Meningiomas, Pituitary gland and Pineal gland Tumors, Primary CNS Lymphomas, Medulloblastomas, Craniopharyngiomas, and Schwannomas.³ The five most frequent tumors were astrocytoma (47.3%), Medulloblastoma (11.4%), craniopharyngioma (9.7%), ependymal tumors (4.8%), and nerve sheath tumors (4.1%). The tumor spectrum varies among different ages and sexes. According to the Central Brain Tumor Registry of The US (CBTRUS) data, glioblastoma (17.7%) and anaplastic astrocytoma (2.1%) were the most common malignant tumors in adults, whereas Medulloblastoma, germ cell tumors, and glioblastoma are more common among children and teenagers.⁴

MATERIALS AND METHODS

This is a single institute ecological study. All the patients of CNS tumours who attended the Department of Radiation Oncology, SAMC, and PGI from October 2010 to December 2019 are included in the study. Total 595 patients attended our Out patient Department (OPD) over these 10 years. All patients have treatment and follow-up data available in their medical charts, which were extracted for this study, and evaluated using a number of potential predictors of survival based on age, gender, primary tumor stage, control of primary tumor, post-operative tumor volume, after the approval from the ethical committee of the institution. The records of 238 patients could be evaluated, and only 102 patients were fit for the study as per the inclusion criteria, i.e., they completed definitive treatment as per their histology and exclusion criteria, i.e., the patients with a mode of death other than the progression of disease were excluded. The survival was confirmed by telephonic or physical follow-up and assessed using the Kaplan - Meier method.

RESULTS

The medical records of 238 patients were evaluated, out of which only 102 were fit for the study as per the inclusion and exclusion criteria. Out of 102, 41% are female, and 59% are male; hence our study showed a higher incidence to be in males than in females. The glioma being the most common histology, we got 75% of patients

with glioma including all the histologies, 8% of Brainstem glioma, 5% pituitary adenoma, 4% medulloblastoma, 3% recurrent Meningioma, 2% meningioma, 2% pituitary craniopharyngioma and 1% pineoblastoma. The most commonly seen patients were of grade II among all histologies. The most common location of the tumor was frontoparietal or parietal lobe.

In our study, maximum survival was seen among patients from 21 - 40 years of age, i.e., middle aged people with 44.1% among the 31 - 40 years age group followed by 26.5% among the 21 - 30 years of age group. The 3 - year median overall survival (OS) of 8 years is shown. (Fig. 1) and Progression Free Survival (PFS) of 7 years (Fig. 2), while the 5

Fig. 1: 3-year Overall Survival

Fig. 2: 3-year Progression-Free Survival

- year median OS of 9 years (Fig. 3) and PFS of 7 years are recorded. (Fig. 4).

Fig. 3: 5-year Overall survival

Fig. 4: 5-year progression-free Survival

Glioblastoma (GBM) is the most aggressive out of all histologies, with a 2-year survival of 31% and a median OS of 8 months, as per our study. We got some good results with brainstem glioma as well, with a 2-year survival of 40% and a median OS of 18 months. In patients with glioma or astrocytoma, grade II was the dominant histology with 77% of 3-year survival. The maximum survival was

seen among patients from 31 - 50 years of age, i.e., middle aged people, with 31.7% among the 31 - 40 years of age group followed by 26.8% among the 41 - 50 years of age group as shown. (Fig. 5) On the basis of sex, females had better survival than males, with 42% of survival. The patients with lesser or no post-operative residual volume had better survival, with 73.5% of survival.

DISCUSSION

According to a study by Kimberly R *et al.*, over 18,000 CNS tumour patients, the male and female populations with malignant tumour were almost similar, with higher 2-year and 5-year survival in

females⁵, while in our study, we had 59% males and 41% females with a 3-year survival of 42% among females and 40% in males.

In a study done by Brigitte Schlehofer *et al.*, menopausal women had a higher risk of glioma than pre-menopausal women, whereas intake

of female steroid hormones was significantly associated with a decreased risk of glioma.⁶ As per their data, the pediatric population comprised 7% of patients with a higher survival rate, and the geriatric population with 37% of patients and lowest survival rate. Among adults, the maximum number of patients were above 35 years of age, with maximum survival rates among 20 to 34 yrs of age. In our study, incidence among pediatric and geriatric populations were found to be the lowest, with insignificant data on their survival. The maximum number of patients were between 21 - 40 years of age, showing maximum survival rates of survival.

The presence of contrast enhancement on Magnetic Resonance Imaging (MRI) is even used as a criterion to discriminate anaplastic oligodendrogliomas from low grade oligodendrogliomas. In our study, however, 23% of low grade tumors showed contrast enhancement, while 35% of high grade tumors had no visible contrast enhancement. As per studies, in grade II and grade III gliomas, the non-enhancing component represents the maximum proportion of the whole tumor (Fig. 6), and it can be

Fig. 6: Showing MRI of Oligodendroglioma grade II

demonstrated by comparison of Fluid Attenuated Inversion Recovery (FLAIR) and contrast enhanced T1 weighted images. The gliomas with high grade lesions are heterogeneous in appearance, and gene

expression with ill-defined boundaries, and the breakdown of the blood brain barrier leads to an increase in enhancement and vasogenic edema. The glioblastomas are associated with epidermal growth factor receptor amplification and are associated with larger enhancing components (Fig. 7) and ill-defined margins.⁷

Fig. 7: Showing MRI of Anaplastic Astrocytoma

In a literature search conducted by Nadir Sanai *et al.*, including a data base from January 1990 to December 2007, adult patients with hemispheric glioma were identified. In most of the studies, the extent of resection (EOR) was defined on the basis of gross total versus sub total resection, and the effect of a greater EOR was more pronounced in the low grade glioma studies, in which the mean survival increased from 61.1 to 90.5 months than the high grade gliomas, in which the survival increased from 64.9 to 75.2 months in WHO Grade III gliomas and from 11.3 to 14.2 months in WHO Grade IV tumors.⁸ In our study, we included only the patients who underwent surgery followed by definitive radiation; the postoperative CT scan or the radiotherapy planning CT scan was looked for the post-operative volume, and the survival was calculated as per the post-operative volume, which was found to be 73.5% including all histologies and grades of tumor, in patients who had lesser or no post-operative residual volume, hence concluding better survival among patients who underwent complete resection.

The standard management of high grade glioma in the form of maximal safe resection followed by adjuvant radiotherapy (RT) along with concurrent Temozolomide (TMZ), followed by 6 – 12 cycles of adjuvant TMZ has been well established in the last decade. TMZ for radical treatment of newly diagnosed GBM was introduced in 2001 at TMH, with the first Indian data reported in 2007, which revealed 2 years survival rate of 28%, consistent with the Stupp's results of the land mark European Organisation for Research and Treatment of Cancer/National Cancer Institute of Canada study.⁹

Comparing our results with the temozolomide arm of the study by Stupp *et al.* The 3-year OS and 5-year OS rates of 58% and 42%, respectively, in our study reveal comparable results. Though the design of the trial by Stupp *et al.* was different from

this study, and a strict comparison of the results cannot be done, the results seem to be comparable. The study by Stupp *et al.* is a randomized multi-institutional trial that included only patients of glioblastoma, while our study is a single arm retrospective but mono institutional, including all the histologies and grades of CNS tumors, and the median age of our patients is less than those in the study by Stupp *et al.* Median overall survival in our patients, including all histologies, is 8 years, and for GBM and brainstem glioma is 8 months and 18 months, respectively. We compared our results and compiled the data of various Indian studies done on post-operative adjuvant radiotherapy along with Temozolomide given in the histologically proven cases of different types of glioma and glioblastoma. (Table 1).

Table 1: Showing Comparative data of Indian Studies Done over on post-operative adjuvant radiotherapy along with Temozolomide given in the histologically proven cases of different types of glioma and glioblastoma.

Author	Histology of included patients	Number of patients included	Treatment strategy	Median OS (in months)
Jalali <i>et al.</i> ¹⁰	GBM	42	RT+TMZ+ 6# TMZ	16.4
Anand <i>et al.</i> ¹¹	High-grade glioma	46	RT+TMZ+ 6# TMZ	15
Julka <i>et al.</i> ¹²	GBM	215	RT+TMZ+ 6# TMZ	13
Jalali <i>et al.</i> ¹³	Brainstem Glioma	20	RT+TMZ(54Gy/30#)	9.15

CONCLUSION

Our study showed a higher incidence of brain tumours in male population, more commonly seen in the middle aged population. The most commonly found histology is glioma, and GBM having the worst prognosis among all the histologies. The patients with lesser or no residual post-operative volume had a better prognosis; hence, the better the resection, the better the survival. Concurrent chemoradiotherapy with TMZ followed by additional cycles of TMZ yields encouraging outcomes, even in our patient population without significant toxicity, validating the published results.
