Abstract

A growing need for sustainable solutions is one of the primary drivers of the demand for industrial enzymes. One of the most significant and beneficial sources of many enzymes has been and still is the microbial world. Numerous industrial procedures, such as chemical synthesis used to create chemicals and pharmaceuticals, have a number of drawbacks: Lack of enantiomeric specificity for chiral synthesis, low pH, high pressure, high temperature, and low catalytic efficiency. Enzyme research and interest are still advancing, which helps industrial biocatalysis succeed even more. There should be a lot of intriguing discoveries in the field of biotransformation over the coming years. The value of biotechnologically and industrially significant microbial enzymes is the main topic of this study, which comprises 44 papers, including research studies and review articles. Also, it offers novel insights into the micro-organisms that manufacture these enzymes as well as the procedures employed for their purification and separation.

Keywords: Microbial Enzymes; Diagnostics; Lipases; Industry; Bio-Remediation; Medicines; Agriculture; Genetic engineering.

INTRODUCTION

An important family of biomolecules called enzymes is required for the many chemical inter conversions essential to life. They perform the unique function known as biological catalysts, which has the amazing capacity to accelerate reactions more rapidly and effectively. They also quicken all bodily metabolic processes.^{1,2,20} Enzymes have piqued the interest of several businesses since they may be utilised to create products for a number of uses and have been the focus of numerous studies over the years. Enzymes are found in the human body, animals, plants, and the flora and fauna of microbes. The enzymes produced by bacteria have been found to serve a variety of biological purposes, and as a result, they are utilised in a wide range of applications.^{24,24} Additionally, they demonstrate that a large portion of this product (enzymes) may be produced by suspension culture, which is why microorganisms are considered to be reliable sources for enzyme production and acquisition. In addition to their inherent biochemical diversity, microbial strains can be genetically modified to create desired chemicals.^{5,6,37}

Fig. 1: Versatile Properties of Microbial Enzymes²⁵

Application of Microbial Enzymes in Medical Health and Diagnostics

The importance of medical care and diagnostics cannot be disputed. They are an essential part of our lives since they improve patient care, protect health, and rapidly spot any possible problems. How to employ therapies and drugs to treat and prevent disease is a challenging subject to tackle. Pre-requisites include a diagnosis and fast, easy, and efficient medication. Microbial enzymes fulfil the three E's, and several studies have shown that these enzymes are highly efficient in the fields of medical health and diagnostics. Maude B. Wikstrom *et al.*, 1983, tested 116 strains for their capacity to produce fibrinogen and fibrin degrading enzymes using blood samples obtained from subjects with angular cheilitis, subgingival plaque on teeth, teeth with infected necrotic pulps, and dental alveoli after surgical removal of mandibular third molars. The most common strains were Actinomyces, Bacteroides, Fusobacterium, Peptococcus, Propionibacterium, and Staphylococcus aureus. Actinomyces, Bacteroides, and Fusobacterium strains with degrading activity are rare. Fibrinogen was degraded by more strains than fibrin, suggesting that a number of proteases may be involved in this process. Furthermore, plasminogen activity was detected in isolates of Clostridium, S. aureus, and Streptococcus pyogenes. According to the study, bacteria create the enzymes necessary to degrade fibrin and synthesise fibrinogen. The importance and use of microbial enzymes for peptide synthesis, as well as the advancement of biotechnological methods, are highlighted by Kumar Dinesh et al. in their 2005 study. According to reports, microbial enzymes can be employed to make peptides and treat various disorders that are hormonal and non-hormonal. Several medical applications of microbial enzymes were outlined by (Irwin W. Sizer et al., 2008). The main take aways are the use of microbial enzymes in blood coagulation, inflammatory treatment, and diagnostics. A description of the microbial enzymes employed in clinical laboratories for quantitative chemical assays and in the treatment of cancer is highlighted in the chapter. Microbial enzymes can be utilised to treat a variety of life threatening illnesses like diabetes, infections, and cardiac arrest when paired with other drugs like antibiotics. Due to their great specificity and quick acting qualities, they can also be utilised to conduct testing. Paul J. Weimer discussed the various medical applications of microbial enzymes. The main take aways are the use of microbial enzymes in blood coagulation, inflammatory treatment, and diagnostics. A description of the microbial enzymes employed in clinical laboratories for quantitative chemical assays and in the treatment of cancer is highlighted in the chapter. Microbial enzymes can be utilised to treat a variety of life threatening illnesses like diabetes, infections, and cardiac arrest when paired with other drugs like antibiotics. Due to their great specificity and quick acting qualities, they can also be utilised to conduct testing. The possibility that ruminant cellulose will be better utilised and that digestive improvements will take place may increase with increases in digestible fodder and enhanced rumen microbial strains and types. Hemerhorst's study provided the first proof of gluten degrading microorganisms linked to the upper GI tract and their function in the digestion of dietary gluten because these salivary microorganisms exhibit glutamine endoprotease activity, which was discovered towards glutamine and proline rich salivary proteins. The main objective was to determine whether gliadins could serve as substrates for the enzymes made by oral microorganisms. The oral microbes proved they could do this by analysing the effects of suspended dental plaque on the proteolytic activity of gliadin derived pNA linked synthetic enzyme substrates. A combination of highly immunogenic gliadin peptides that are produced both naturally and artificially; (33-mer of a2-gliadin and 26-mer ofcgliadin).

Using gliadinzymography, it was also possible to determine the estimated molecular weights and pH activity profiles of the oral enzymes that degrade gliadin. Using liquid isoelectric focusing, the enzymes' total isoelectric points were calculated. Preferentially, the tripeptide YPQ, which is typically present in gluten, is targeted.

As representative gliadin derived substrates, Anaspec in Fremont, California, chemically developed four synthetic analogues: Z-YPQpNA, Z-QQP-pNA, Z-PPF-pNA, and Z-PFP-pNA. The bulk of the oral gliadin degrading enzymes were acidic, and it was demonstrated that gliadin degrading enzymes were active over a wide pH range. We observed the proteolytic degradation of gliadin and two other highly immunogenic and protease resistant gliadin peptides. Intriguing genetic parallels between PRPs made from human saliva and gliadins made from wheat were also discovered by the study. In humans, the mouth cavity serves as a breeding habitat for bacteria that facilitate digestion by secreting enzymes that break down gliadin. Therefore, by detoxifying immunogenic gluten peptides, these bacteria and enzymes may result in new treatments for people with celiac disease as well as other disorders. Proteolytic enzymes and treatment procedures help break down gluten. Human oral cavity bacteria and relevant enzymes may enable some novel strategies to detoxify immunogenic gluten peptides and treat patients with celiac disease and other gluten related illnesses. Flint J. Harry and others in 2012 investigated the symbiotic relationship & impact of dietary carbohydrate and prebiotics on human health with the application as a new platform of study of human health, particularly among members of the under studied Firmicutes phylum. The fermentation of complex carbohydrates in the intestine is carried out by a few dominant species among the Bacteroidetes, which owns very large numbers of genes encoding (CAZymes). The microbes in the gut play crucial functions by dissolving complicated substrates. The mammalian intestine is home to bacteria, which have a wide variety of genes and degradative enzymes in their arsenal. It may be possible to identify, characterize, and comprehend the many functions that these bacteria, fungi, and hosts play in metabolic outputs and applications. (Essam Kotb et al., 2013) found that both the methods for measuring fibrinolytic activity and the microorganisms that produce those enzymes were discussed in the literature. It is possible to show how microbial

fibrinolytic enzymes are used in the treatment of myocardial infarction and other cardiovascular diseases. Elizabeth Culp and others discussed the prospects and advancement in the development of medications targeting bacterial proteases, with a particular emphasis on AAA+ proteins family proteolytic complexes. (SPs). The importance of bacterial enzymes, which are essential in the establishment of resistance, was emphasized. Bacterial proteases may prove to be a wealth of new antibiotic targets in the future. Based on their roles in various metabolic pathways, these enzymes are divided into several categories. Important findings include the enzymatic alteration of intracellular targets, the enzymatic transformation of antibiotics, antibiotic resistance, enzymes, mutant forms, and antibiotics (Table 1 & 2). It is feasible to predict and assess that bacterial enzymes are a fantastic research topic for microbiologists, molecular biologists, and biotechnologists, and employ it in metabolizing antibiotics as drugs.

Microbial Enzyme Application Baking, brewing, liquefaction of starch enhancing the quality of bread a-Amylase Rice cakes Clarification of fruit juice Glucoamylase Manufacturing beer Bread quality improvement High glucose and high fructose syrups Protease Brewing Meat tenderization Coagulation of milk Bread quality improvement Lactase (β-galactosidase) Lactose intolerance reduction in people Prebiotic food ingredients Lipase Cheese flavor enhancement Cheddar cheese production Phospholipase Cheese flavor enhancement Production of lipolyzed milk fat Esterase Enhancement of flavour and fragrance in fruit juice De-esterification of dietary fibre Production of short chain flavour esters Cellulase Animal feed Clarification of fruit juice Xylanase Clarification of fruit juice, Beer quality improvement Pectinase Clarification of fruit juice Food shelf life improvement Glucose oxidase Food flavor improvement Laccase Polyphenol removal from wine Baking Catalase Food preservation (with glucose oxidase) Removal of hydrogen peroxide from milk prior to cheese production Peroxidase Development of flavor, color and nutritional quality of food a-Acetolactate dehydrogenase Shortening maturation of beer Asparaginase Reduction of formation of acrylamide during baking Removal of bitter taste in fruit juice Debittering enzymes - naringinase Wine aroma enhancement

Table 1: Applications of microbial enzymes in Various industries

<u> </u>	Microbial Species, Types and	
Saccharomyces cerevisiae	Yeast	Bakery, wine, beer, sake
Saccharomyces carlsbergensis	Yeast	Light beer
Saccharomyces rouxii	Yeast	Soy sauce
Candida milleri	Yeast	Sour dough French bread (sour bread)
Lactobacillus sanfrancisco	Bacteria	Sour dough French bread (sour bread)
Streptococcus thermophilus	Bacteria	Yogurt
Lactobacillus bulgaricus	Bacteria	Yogurt
Propionibacterium shermanii	Bacteria	Swiss cheese
Gluconobacter suboxydans	Bacteria	Vinegar
Penicillium roqueforti	Filamentous fungi	"Roquefort" cheese
Penicillium camemberti	Filamentous fungi	"Camembert" and "Brie" cheeses
Aspergillusoryzae	Filamentous fungi	Saké
<i>Rhizopus</i> sp.	Filamentous fungi	Tempeh
Mucor sp.	Filamentous fungi	Sufu (microbial rennet)
Monascus purpureus	Filamentous fungi	Ang-kak (red rice)
S. cerevisiae	Yeast	Ethanol (from glucose)
Kluyveromyces fragilis	Yeast	Ethanol (from glucose)
Clostridium acetobutylicum	Bacteria	Acetone and butanol
Xanthomonas campestris	Bacteria	Polysaccharides
A. niger	Filamentous fungi	Citric acid
C. glutamicum	Bacteria	l-Lysine, 5-inosinic acid, 5-guanylic acid
	Single Cell Proteins (SC	Р)
Candida utilis	Yeast	SCP from paper industry waste cultivation
Yarrowia lipolytica	Yeast	SCP from alkane cultivation
Methylophilus methylotrophus	Bacteria	SCP from methane or methanol cultivation
Candida utilis	Yeast	SCP from paper industry waste cultivation
Methylophilus methylotrophus	Bacteria	SCP from methane or methanol cultivation
	Vitamins and Enzymes	
Pseudomonas denitrificans	Bacteria	Vitamin B12
Propionibacterium	Bacteria	Vitamin B12
Eremothecium ashbyi	Yeast	Riboflavin
Pseudomonas denitrificans	Bacteria	Vitamin B12
Propionibacterium	Bacteria	Vitamin B12
Trichodermareesei	Filamentous fungi	Cellulase
S. cerevisiae	Yeast	Invertase
K. fragilis	Yeast	Lactase
S. lipolytica	Yeast	Lipase
Bacillus	Yeast	Protease
Aspergillus	Yeast	Pectinase and protease
Endothiaparasitica	Yeast	Microbial rennet
Eremotheciumashbyi	Yeast	Riboflavin
Pseudomonas denitrificans	Bacteria	Vitamin B12
Propionibacterium	Bacteria	Vitamin B12
Trichodermareesei	Filamentous fungi	Cellulase
S. cerevisiae	Yeast	Invertase

Application of Microbial Enzymes in Pharmaceutical, Food, Textiles, Agrochemical Industries that secreted a proteolytic enzyme in an organic solvent medium was identified as Pseudomonas aeruginosa, according to a 1995 study by Hiroyasu Ogino *et al.* A high rate proteolytic enzyme producer was initially isolated using the conventional

Food and Textiles Industry: A bacterial strain

66

method, and then an organic solvent tolerant microbe was selected from this group of high rate proteolytic enzyme producers to create the strain. The culture's supernatant's proteolytic activity was examined in organic solvents, and it was found to be stable. The stability of the enzyme was essentially the same when there were no organic solvents present when the values of the partition coefficient's logarithm (log P) were equal to or higher than 3.2.³ When various organic solvents are available, the enzyme and solvent stable bacterium of this strain can both be employed as catalysts. With the use of recombinant DNA technology, special enzymes that are appropriate for specific food processing scenarios may now be produced. In a study by Zofia S. Olempska Beer et al., the manufacture and safety assessment of enzyme preparations, the generation of recombinant production strains, approaches for improving enzyme properties, and the safety of microorganisms used as hosts for enzyme encoding genes are briefly discussed by removing native genes encoding extracellular proteases, it is possible to construct microbial and fungal strains specifically for the production of enzymes and modify them to reduce or eliminate their capacity to make toxic secondary metabolites. This increases the yield of the enzymes produced. The potential for oxidative enzymes with high efficiency, inherent stereo and regioselectivity, and stereo and regioselectivity to operate as biocatalysts for different biotechnological processes was highlighted, according to (F. Sima Sariaslani et al., 20080). It is obvious that microbial enzymes have uses in a variety of businesses, including those that specialise in genetic engineering.

Fermentation Industries: According to a 2016 study by Giyatmi et al., a variety of enzymes are examined along with their relevance, including natural fish enzymes, fermented fish products, microbial enzymes, and muscle tissue enzymes. It is shown how the fermentation process works with microbial enzymes derived from fish. In addition, (Bowen Wang et al., 2010) reported that they investigated the activity of enzymes from Aspergillus, Rhizomucor, and Rhizopus and used metaproteomics to find 51 carbohydrate hydrolases in the fermentation of Chinese spirits. The prospect of conducting additional studies on fermented fish is also explored. Dark fermentation is a technique utilised by Prakash K. Sarangi et al., 2020 to create bio hydrogen from waste biomass. The key finding of dark fermentation showed how well microbial enzymes can ferment biomass to produce biofuels from waste. They talked about various biological hydrogen generating systems as well as process

parameters. The carefully selected bacterial and fungal strains can be used in industrial manufacture. Because amylases are essential for turning starches into oligosaccharides. The study maintains starch as a significant element because it is a staple food for humans and a storage product of numerous crops, including wheat, tapioca, and maize. The emphasis of the article is on the structural and functional characteristics, distribution, and production of amylase using submerged fermentation and solid state fermentation methods to illustrate its properties, including thermo stability, pH, and purification using chemical and physical factors. Amylase is one of the primary enzymes used in industrial processes like food production, fermentation, etc. A wide range of plants, animals, and microorganisms can produce amylases. Microbial pectinases are a group of enzymes that have potential applications across a range of sectors, according to the literature. These enzymes are widely used in a range of industries, including the wine, food, and paper industries, and are thought to be environmentally safe. The extracellular thermostable alkaline protease was demonstrated to be produced from the A10 strain by (Yilmaz Bahar et al., 2015). The A10 strain was purified 1.38-fold with 9.44% efficiency using DE52 anion exchange chromatography and ammonium sulphate precipitation dialysis. The study's guiding principles are the purification and characterization of the alkaline protease enzyme from the thermophilic bacterium B. licheniformis A10. According to investigation, A10 protease enzyme displays excellent activity and stability at high temperatures and pH levels and can be employed in a number of industrial processes.9 Noura Raddadi et al., 2015) discussed the ecology and most current biotechnological applications of microbial extremophiles, extremozymes, and extremolytes. Microorganisms that produce extremozyme and extremolytes are valuable resources for the development of a bio-based economy.

Pharmaceutical Industries: New studies into novel bacteria that can be used to produce amylase would be very advantageous for the pharmaceutical, starch based, and therapeutic industries Including Daljit Singh Arora, In order to better understand the mechanisms underlying the reactions of interest and to maximise laccase's catalytic activity for usage in a variety of biotechnology applications, the study uses multiple physiochemical parameters to interpret laccase synthesis. Microbial enzymes can be utilised to modify synthetic chemicals for pharmaceuticals and agricultural applications since chiral intermediates and fine chemicals are highly sought after by the pharmaceutical and agrochemical industries. (Patel, Ramesh N., 2002) detailed the microbial and enzymatic processes in his study and synthesised chiral intermediates for the treatment of cancer, viruses, hypertension, melatonin receptor agonists, high cholesterol, and Alzheimer's disease using enzymes derived from bacteria.

Chemical and Agro Chemical Industries: The best substitute (BGL) that the fungus creates, according to Tiwari Pragya et al., are the microbial enzymes. Trichoderma collaborates to completely hydrolyze cellulose in order to produce biofuel as a solution to the energy issue. Numerous modification strategies, such as the development of glucose tolerant (BGL) and external delivery in conjunction with other celluloses, are used in the bulk of current applications for (BGL). A few major microbial enzymes are reviewed by Nigam Singh Poonam in a study done in 2013 along with their distinctive characteristics and commercial relevance. Over the years, scientists have isolated and documented a range of specialised bacteria from extreme sources to see if these microbes are capable of biosynthesizing particular enzymes. To produce high-quality enzyme preparation on a large scale for various commercial uses, a varied range of enzymes are being synthesised employing chosen microorganisms with specific properties. Biotechnology is starting to be seen as a solution to several global issues. The study of microbial enzymes and the techniques used to make them have improved large yields of enzymes with useful specific qualities, such as thermal stability, tolerance to high temperatures, and stability in acidic or alkaline conditions. Mohamed A. Hassan and others in 2015 studied that Both the Bacillus amyloliquefaciens MA20 and Bacillus subtitles MA21 soil isolated strains were discovered in their study. Study of their morphological, biochemical, and molecular characteristics revealed that they were sensitive to PMSF and that they produced serine proteases that were stable in organic solvents and only slightly inhibited by EDTA. Because the two proteases created in the study are metal enhanced and stable in the majority of organic solvents, they can be exploited in biotechnological applications like the wool industry. Aspergillus Niger, a fungus that originated in a maritime environment, was the subject of research by Ghada E. A. Awad et al. in 2015. In order to create gel beads that were biocatalytically active, Aspergillus Niger's induced naringinase was immobilised. Immobilization and E.L.C., chemical, and physical characterisation optimisation were the main

subjects of the investigation. The immobilisation process greatly improved the enzyme's thermal stability, which is helpful in the food sector. On a commercial as well as an industrial level, these results are quite beneficial. The findings paves the way for further investigation and aids in the production of immobilised naringinase for use in applications beyond marketing and industry. Girvan M. Hazel and others (2016) said that the role of wild type and modified P450s in the production of major chemicals, including drugs and drug metabolites, steroids, antibiotics, and members of the CYPs super family, is discussed in the article. It is clear that CYPs are crucial for synthetic biology. Vildan Yildirim and others (2017) in a study done on the extracellular thermostable alkaline serine protease enzyme was biochemically isolated, characterised, and purified 4.85 and 17.32 times, with a yield of 26.9 and 19.56%, respectively, using DE52 anion exchange and probond affinity chromatography. It was revealed that the enzyme activity was retained at levels more than 70% and 55%, respectively, in the presence of organic solvents and commercial detergents. As can be shown, pure protease enzyme may be preferred for commercial applications that require long-term stability at high temperatures. A. pallidus C10 alkaline protease is a great detergent additive in a number of commercial and biotechnological fields, particularly the detergent industry. The yields of fourteen model enzymes in E. coli cultures cultured in fresh, ambiguous media and in complicated media were rigorously compared in the study by Lukas Chrast et al. (2017). In conclusion, the experimental innovative semi-defined medium offers shake flask protein yields without the need for costly bioreactor purchases. All of the studied enzymes expressed in enzymatic fed batch like cultures showed improvements in the volumetric yields without significantly affecting the structure, stability, or activity of the enzymes. Rodrigues, Ronivaldo da Silva in 2017 demonstrated the biochemical and biotechnological characteristics of the seven various types of catalytic types with an emphasis on new studies, production, catalysis, and uses of these enzymes. The discovery makes it simpler to develop new enzyme based goods with applications in food, medicine, basic science, and bioactive peptides. Among others, Abdul Razzaq (2019) Comparedvarious proteases and contemporary issues with industrial production and use are the review's main focuses. Microbial proteases might be offered economically and commercially on a global scale if these problems were solved. For industries with widespread use

(Table 3), like textile, pharmaceuticals, leather, food, and detergent, the interpretation is fully dependent

on microbial enzymes.

Industry	Enzyme	Function	Microorganisms
Dairy	Acid proteinase	Milk coagulation	Aspergillus sp.
	Neutral proteinase	Faster cheese ripening, debittering	Bacillus subtilis, A. oryzae
	Lipase	Faster cheese ripening, flavor customized cheese,	Aspergillusniger, A. oryzae
	Lactase (β -galactosidase)	Lactose reduced milk and whey products	Escherichia coli, Kluyveromyces sp.
	Aminopeptidase	Faster cheese ripening	Lactobacillus sp.
	Catalase	Cheese processing	Aspergillusniger
	Transglutaminase	Protein cross linking	Streptomyces sp.
Baking	Amylase	Flour adjustment, bread softness	Aspergillus sp., Bacillus sp.
	Maltogenic a-Amylase	Enhance shelf life of breads	Bacillus stearothermophilus
	Xylanase	Dough conditioning	Aspergillusniger
	Lipase	Dough stability and conditioning	Aspergillusniger
	Glucose oxidase	Dough strengthening	Aspergillusniger, Penicilliumchrysogenum
	Transglutaminase	Laminated dough strength	Streptoverticillium sp., streptomyces sp.
Beverage	Pectinase	Depectinization	Aspergillusoryzae, Penicilliumfuniculosum
	Glucose oxidase	Oxygen removal from beer	Aspergillusniger
	Cellulase	Fruit liquefaction	Aspergillusniger, Trichodermaatroviride
	α-Amylase	Starch hydrolysis	Bacillus, Aspergillus
	β-Amylase	Starch hydrolysis	Bacillus, Streptomyces, Rhizopus
	β-Glucanase	Restrict haze formation	Bacillus subtilis, Aspergillus spp.
	Protease	Restrict haze formation	Aspergillusniger
	Pullulanase	Starch saccharification	Bacillus sp., Klebsiella sp.
	Naringinase	Debittering	Aspergillusniger
	Limoninase	Debittering	Aspergillusniger, A. oryzae
	Aminopeptidases	Protein breakdown during mashing	Lactobacillus brevis, L. plantarum
Animal feed	Phytase	Hydrolyze phytic acid to release phosphorous	Aspergillusniger
	Xylanase	Enhanced digestibility of starch	Aspergillus sp., Bacillus sp.
	β-glucanase	Digestive aid	Aspergillusniger

Application of Microbial Enzymes in Agricultureenvironmental Monitoring, Bio-Remediation

According to Naoto Ogawa's 2003 statement, a lot of study has been done on the genetic relationships, regulation strategy, function, and evolution of microbial genes and enzymes. The microbial degradation of chlorobenzoates, chlorocatechols, and chlorophenoxyacetic acids is discussed in this review with emphasis on the genetic structure, the regulation of gene expression, and evolutionary considerations. Numerous chlorinated compounds are produced by the chemical industry, and the release of such substances into the environment has led to serious environmental problems. One of the causes of this contamination is the inability of natural bacteria to efficiently break down manmade chlorinated compounds. Microorganisms are remarkably adaptable to environmental changes, which has led to the development of genes that specify the breakdown of chlorinated chemicals to

varying degrees. It is evident that the environmental contamination brought on by the chemical industry's production of numerous chlorinated compounds and subsequent release into the environment has made it challenging for natural microbes to efficiently break down manufactured chlorinated chemicals. Genetic engineering, however, can enable them to efficiently break down manmade chlorinated chemicals, which are in charge of global pollution. With an emphasis on this procedure, (Wanpeng Wang et al., 2013) described how bacteria now metabolise long-chain alkanes aerobically. The regulation of alkane degrading genes, early oxidation, chemo taxis to alkanes, and other factors are all factors that the authors take into consideration. Alkanes and hydrocarbons are two contaminants found in the atmosphere. There are some yeasts, filamentous fungi, and microorganisms that are particularly good at degrading alkanes. It is possible to increase the likelihood of removing contaminants based on alkanes that are harmful to living systems by studying the microbial

activity of certain microorganisms as well as the fundamental mechanisms of bacterial alkane dependent chemotaxis, alkane transport, and gene expression regulation. (Gajendiran Anudurga., 2016) The examination into the degradation of DPE by A. clavatus was seen during a period of 90 days of incubation in aqueous medium. Changes in polyethylene weight, CO₂ development using the Strum test, infrared spectra, and infrared spectra all showed signs of degradation. Morphological changes were also discovered by SEM and AFM studies. A. Clavatus is a suitable option for the degradation of LDPE, however more research is needed to support the applications. Zhang W, Lin Z, and others (2020) The main areas of research attention were the screening of lindane (Pesticides)degrading strains and the analysis of degradation products in lab settings. The supporting technologies and procedures for microbial degradation based bioremediation ought to be created and widely applied. By producing extracellular and intracellular enzymes that break down lindane into less hazardous and nontoxic chemicals, the study found that microbial metabolism can effectively break down lindane. Similar to this, specific bacterial strains may influence how various pesticides and insecticides degrade. For instance, lindane degrades differently depending on the microorganisms that break it down. The breakdown of lindane is known to involve several strains of Microbacterium sp. P27, Paracoccus sp., and Phragmites karka. et al. Haldar Shyamalina et al., 2020). The essay examines Abhijeet Al's (2017) studies on xylanase control and their potential industrial applications, with a focus on pulp bioleaching and the reduction of environmental pollution, as well as the microbial enzyme complex that completely breaks down xylan down, and discusses the accumulation of HM in aquatic environments in India. Our knowledge of the roles and repertoire of the enzyme, which is found in numerous bacteria, will grow as a result of research on extreme temperature enzymes and cutting edge technologies like genome sequencing.

CONCLUSION

Applications for microbial enzymes can be found in a wide range of industries, such as chemical, fermentation, agriculture, medicines, and food manufacturing. Recombinant enzymes have been expressed in bacteria, filamentous fungus, and yeasts; choosing the right expression systems is crucial for the rate of enzyme production. The benefits of these species have led to an increase in the number of biotechnological applications. Nevertheless, physiological effects make it challenging to produce high level expression of recombinant enzymes. The natural enzymes have drawbacks, particularly in industrial settings include limited activity, stability, and catalytic effectiveness. To get around these restrictions, techniqueslikesitedirected mutagenesis, truncation, and terminal fusion have been employed. One thing is clear from all the research done over the years: microbial enzymes are extremely important both physiologically and commercially. They have both synthetic and degradative qualities. These can be found in microorganisms, plants, and animals. However, microorganisms are the preferable supply because they are a treasure trove of different enzymes. The hunt for better strains of the microorganisms employed in the industry and an irreplaceable resource for biotechnological developments both depend heavily on biodiversity. Because enzymes are environmentally neutral and don't produce greenhouse gases or energy intensive waste products, they are replacing chemicals in many industrial production processes. Microbial sources of enzyme production are the most preferred source for industrial enzyme production because the microbes are easily accessible, they grow at a very fast rate, and they can be genetically modified to produce enzymes that can perform optimally at different industrial production conditions. This helps the microbes survive the harsh production conditions and meet the ever increasing demand for enzymes in many industries. Microbial enzymes are exceedingly adaptable and have applications in a wide range of industries, including those in the textile, leather, paper and pulp, research and development, pharmaceutical, agricultural, detergent, waste, biorefineries, photography, and food sectors. People have always been selfish and are constantly seeking for better ways to live. These microbial enzymes' research, efforts, and results are regarded as one of the most promising future options because they are crucial to the diagnosis, therapy, biochemical examination, and monitoring of several terrible conditions. In a very short period of time, modern biotechnology has quickly developed. In a very short period of time, modern biotechnology has quickly developed from a scientific curiosity to a lucrative industry. Because to break throughs in microbiology and biotechnology, it is now possible to create these magnificent enzymes, which will also make it simpler for us to use them in ways that will enhance our quality of life and the environment we live in.
